If the PA0OE is "1", Pin PA0 is an **open-drain** output port. If the PA0OE is "0", Pin PA0 is an input port **without** internal pull-up resistor. The PA1 is the same as the PA0. Fig. 2 shows the structure of PA0.

**Fig.2 Structure of PA0 and PA1**

The PA2 to PA7 are general purpose IO shared with PWM output and some special functions. When the EPWMn is "0" and the special function is disabled, PAn is a general purpose I/O port. If the PAnOE is "1", the PAn is configured as an output port in a push-pull type which can source or sink 6mA. If the PAnOE is "0", the PAn is configured as an input port with internal pull-up resistor.

**Fig.5 Block diagram of sync signal processor**

### Horizontal Frequency Counter

A 13-bit counter is used to measure horizontal frequency.

Name	Addr	R/W	Initial	Bit 7	Bit 6	Bit 5	Bit4	Bit 3	Bit 2	Bit 1	Bit 0
HFREQ_L	0010h	R	xxh	HLVL	HINPOL	HCHG	HFL4	HFL3	HFL2	HFL1	HFL0
HFREQ_H	0011h	R	xxh	HFH7	HFH6	HFH5	HFH4	HFH3	HFH2	HFH1	HFH0

Bit Name	Description
HLVL	"1": Indicates Hsync pin is high level. "0": Indicates Hsync pin is low level.
HINPOL	"1": Indicates Hsync input is positive polarity. "0": Indicates Hsync input is negative polarity.
HCHG	"1": If the H period has been changed.
HFH7~HFH0	Indicates the Hsync frequency in kHz.
HFL4~HFL0	When QUICK="0", HFL4 ~ HFL0 indicates the Hsync frequency in 31.25Hz unit. When QUICK="1", HFL4 ~ HFL1 indicates the Hsync frequency in 62.5Hz.

**Horizontal polarity detect**

The horizontal polarity is detected by sampling HIN signal with a delay time after rising and falling edge of HIN. When the  $126\text{kHz} < \text{HIN}$ , sample level at  $3.5\mu\text{s} - 4.5\mu\text{s}$  after HIN transition edge. When the  $23\text{kHz} < \text{HIN} < 126\text{kHz}$ , sample level at  $5.5\mu\text{s} - 6.5\mu\text{s}$  after HIN transition edge. When the  $\text{HIN} < 23\text{kHz}$ , sample level at  $8.5\mu\text{s} - 9.5\mu\text{s}$  after HIN transition edge.

**Horizontal frequency detect**

User can choose 16ms or 32ms time interval to count pulse number of Hsync every 16.384ms or 32.768ms. For example, if QUICK bit is set, when a 16.384ms time frame begins, it resets the counter and starts counting Hsync pulses till 16ms reached, then loads the counter value to HFREQ\_H and HFREQ\_L registers. If the H frequency is over 192kHz, the H counter will stop counting.

The sync processor interrupt is generated every 16.384ms or 32.768ms for checking H frequency. This interrupt will be cleared after reading the HFREQ\_H register.

**Vertical Frequency Counter**

A 13-bit counter is used to measure the time interval between two vertical sync pulses.

Name	Addr	R/W	Initial	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
VFREQ_L	0012h	R	xxh	VF7	VF6	VF5	VF4	VF3	VF2	VF1	VF0
VFREQ_H	0013h	R	xxh	VLVL	VINPOL	VOVF	VF12	VF11	VF10	VF9	VF8

Bit Name	Description
VLVL	"1": Indicates Vsync pin is high level. "0": Indicates Vsync pin is low level.
VNPOL	"1": Indicates Vsync input is positive polarity. (SEPART in HV_CR1 also make it "1") "0": Indicates Vsync input is negative polarity.
VOVF	"1": Indicates V counter is overflowed. Vsync frequency is lower than 15.25Hz. "0": Vsync frequency is over 15.25Hz.
VF12 ~ VF0	Indicates the Vertical Total Time. Vertical frequency is $[125000 / (\text{counter value} \pm 1)]$ Hz

**Vertical polarity detect**

Vertical polarity is detected by sampling VIN level at 2.048ms after rising edge of VIN. If the level is low, the polarity is positive (VINPOL=1). If the level is high, the polarity is negative (VINPOL=0). But if SEPART bit is set, the VINPOL bit is "1" because the Vsync from composite signal separator is always positive polarity.

**Vertical frequency detect**

It will be updated every vertical frame. The clock of this counter is 125kHz. So the frequency of Vsync is  $[125000 / (\text{counter value} \pm 1)]$  Hz. When V frequency is lower than 15.25Hz, this counter stops counting and set VOVF bit to "1".

Vertical polarity is detected by sampling VIN level at 2.048ms after rising edge of VIN.

**Hsync Period Counter**

The H\_PERD is an 8-bit counter to detect the cycle time of the Hsync input.

Name	Addr	R/W	Initial	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
H_PERD	0014h	R	xxh	HPRD7	HPRD6	HPRD5	HPRD4	HPRD3	HPRD2	HPRD1	HPRD0

This is an 8-bit counter that uses 6MHz clock to measure time interval between two H pulses. If the H frequency is lower than 23437.5Hz, this counter will overflow and register H\_PERD value is zero.

BYPASS	Select bypass the composite signal separator or not. "1" : HOUT pin outputs sync signal bypass the composite signal separator. "0" : HOUT pin outputs sync signal from the composite signal separator.

**Output Polarity Control**

HOPOL and VOPOL bits control the polarities of HOUT and VOUT. When the bit is "1", the output polarity is positive. When the bit is "0", the output polarity is negative.

**HVPASS**

HVPASS will deliver the Hsync and Vsync from HIN and VIN to HOUT and VOUT without polarity changed.

**Composite Sync Signal Separator**

The composite sync signal separator can handle H+V and H exclusive-OR V signals. It will extract Vsync signal from HIN or SOGIN input pin by filtering abnormal pulses. The output Vsync signal will be widened about 4.5~5.5us. The output Hsync will be replaced by 2us pulse during Vsync pulse. Fig.7 shows the relationship of the extracted H and V sync signals.

If inserting the pseudo H pulses (Extracted HS signal) during Vsync pulse is not necessary, set BYPASS bit can make HOUT pin output waveform the same as Hsync input (Note: polarity can be controlled by HOPOL bit), set HVPASS can make HOUT pin output waveform fully the same to Hsync input.

<b>Interrupt Condition</b>	<b>Clear Interrupt</b>
The new H_PERD is not in the old H_PERD ± H_CNT (addr 19h).	Read H_PERD (Addr 14h) to clear this interrupt and HCHG.

**IR interrupt**

<b>Interrupt Condition</b>	<b>Clear Interrupt</b>
Receive DATA.	Read IR_DATA (Addr 43h) will clear this bit.
Receive the REPEAT code.	Write "1" to CLR_KP bit in IR_CTL (Addr 42h) register then write "0" to CLR_KP.
Transmit timing error.	Write "1" to CLR_ERR bit in IR_CTL (Addr 42h) register then write "0" to CLR_ERR.

### A/D Converter

The Analog-to-Digital Converter (ADC) is 8-bit resolution with four selectable input channels. When EN\_CHn is set, PCn is configured as ADC input and PCn pull-high resistor is disabled. When CHn is set, it will reset the ADC\_DA register and start converting. After the conversion is done, the ADRDY bit is set and valid data is stored in ADC\_DA. The total conversion time is 12us. If program wants to make a new conversion, it writes CHn register again and it will start another conversion.
